This final report was prepared by the University of Arizona, Tucson, Arizona, through AFOSR Grant 76-3009, Job Order 12090525 with the Air Force Weapons Laboratory, Kirtland Air Force Base, New Mexico. Capt Howard G. Hudson (ELT) was the Laboratory Project Officer-in-Charge.

When US Government drawings, specifications, or other data are used for any purpose other than a definitely related Government procurement operation, the Government thereby incurs no responsibility nor any obligation whatsoever, and the fact that the Government may have formulated, furnished, or in any way supplied the said drawings, specifications, or other data is not to be regarded by implication or otherwise as in any manner licensing the holder or any other person or corporation or conveying any rights or permission to manufacture, use, or sell any patented invention that may in any way be related thereto.

This report has been reviewed by the Office of Information (OI) and is releasable to the National Technical Information Service (NTIS). At NTIS, it will be available to the general public, including foreign nations.

This technical report has been reviewed and is approved for publication.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number) (UNCLASSIFIED) In this work, the problem of determining the currents excited on a wire enclosed within a rectangular cavity is considered. The wire and cavity interior are excited by electromagnetic sources exterior to the cavity which couple to the cavity interior through a small aperture in the cavity wall. It is assumed that the wire is thin, straight and oriented perpendicular to one of the cavity walls. An integral equation is formulated for the problem in the frequency domain using equivalent dipole moments to approximate the

over

UNCLASSIFIED

SECURITY CLASSIFICATION OF THIS PAGE(When Data Entered)

effects of the aperture. This integral equation is then solved numerically by the method of moments. The dyadic Green's functions for this problem are difficult to compute numerically; consequently, extensive numerical analysis is necessary to render the solution tractable. Sample numerical results are presented for representative configurations of cavity, wire and aperture, and suggestions for future extensions of this work are discussed.

CHAPTER 1

INTRODUCTION

This report has been written to provide documentation to the computer code which numerically implements the theory found in [1] for the electromagnetic excitation of a thin, straight wire in a rectangular cavity which is excited through a small aperture in the cavity wall. Because many of the equations and discussions in [1] are crucial to an understanding of this code, it is assumed that the user has that document available for ready reference.

This code has been prepared for use on a CDC 6400 computer using the RUN fortran compiler. It is also compatable with CDC's FTN compiler. However, for later versions of this compiler it may be necessary to suppress the non-fatal error message "ARGUMENT TOO SMALL" which is detected in EXP. This error will naturally occur during normal program execution and has no effect upon the program output. This error can be suppressed by an appropriate call to SYSTEMC in program START.

In addition, every effort has been made to write the code in standard fortran. However, it is expected that a few minor modifications might be needed for its use on non-CDC machines and with other fortran compilers.

Chapter 2 of this document provides a list and description of all input parameters for this code. Similarly, chapter 3 outlines

the various information which the code returns as output. These two chapters should provide the user with the needed information to operate the code. In addition, chapter 4 discusses the function of each sub-program in the code, and a complete listing of all programs can be found in the appendix.

CHAPTER 2

INPUT PARAMETERS

File INPUT

Note that all of the following parameters are read from the file INPUT in the main program START. All input parameters that represent lengths (A, B, C, XC, YC, R, ZL, ZU, LBDA, XPP, YPP, RA, DELFIX) may be input in any system of units desired, so long as the same unit is used throughout. Also note that if LBDA is set to unity, it has the effect of normalizing all other lengths in units of wavelength.

N -- Number of pulses to be used in wire current expansion

IGRD -- Integer which indicates connection of wire to one or both cavity walls.
If IGRD equals:

0, wire is unattached
-1, wire is attached at $z=0$
1, wire is attached at $z=c$
2, wire is attached at both $z=0$ and $z=c$

A,B,C -- The dimensions of the cavity in the x, y, z directions, respectively (note that cavity must be oriented such that $A \leq B$)

XC,YC -- The x-y coordinates of the center of the wire

R -- The wire radius

ZL,ZU -- The z coordinates of the wire endpoints, with $ZL < ZU$

LBDA -- The wavelength (λ) associated with the frequency of operation

NSM -- Maximum number of terms used for the sum S3

MAX -- Maximum value of m permitted in the sum of
 SUBROUTINE BADSUM (See [1], p. 57-58)

MAXX -- Maximum value of m permitted in the sums of
 subroutines GM1, GM2, and GM3 (See [1], p. 57-58)

CS,LS -- Convergence criteria for all sums (See [1], p. 57-59)

ADYAD -- Logical variable which controls the method in which
 the components of \bar{G}_e are computed. If ADYAD equals:
 (.T.) first-order difference techniques are used
 to calculate \bar{G}_e from \bar{G}_A using equation (2.2) from [1].
 (.F.) components of \bar{G}_e are computed directly

NWALL -- Indicates the cavity wall perforated by the aperture.
 If NWALL equals:
 1, aperture is in $x=0$ wall ($\hat{n}=\hat{x}$)
 2, aperture is in $y=0$ wall ($\hat{n}=\hat{y}$)
 3, aperture is in $z=0$ wall ($\hat{n}=\hat{z}$)

XPP,YPP -- The x_1 and x_2 coordinates of the centerpoint of
 of the aperture, such that $\hat{a}_1 \times \hat{a}_2 = \hat{n}$ (see [1], p. 23)

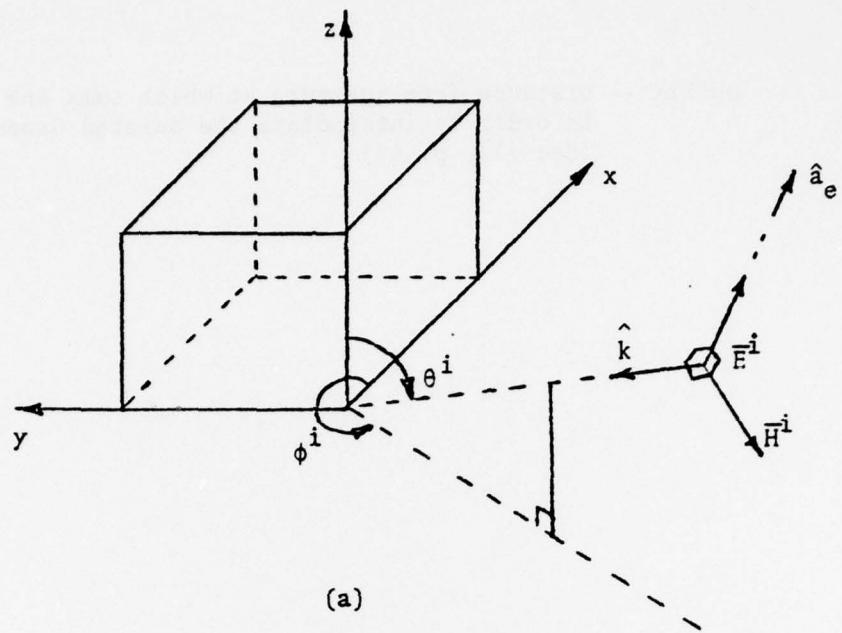

RA -- An array containing the semi-axes of the elliptical
 aperture in the x_1 and x_2 dimensions, respectively

EMAG,PHASAP,THE,PHI,ANG -- Parameters controlling the incident
 plane wave excitation, where

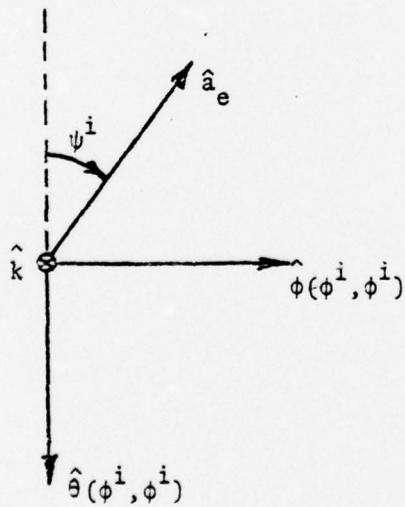

$$\bar{E}^{inc}(\bar{r}) = \hat{a}_e |E_o| e^{-jk \cdot \hat{R}}$$
 where \hat{a}_e and \hat{k} are defined in Figure 1 with

$$EMAG = |E_o|, \text{ THE} = \theta^i, \text{ PHI} = \phi^i, \text{ ANG} = \psi^i.$$
 If PHASAP = (.F.), phase of incident field is referenced
 to the coordinate origin ($\bar{R} = \bar{r}$) and if PHASAP = (.T.),
 the phase is referenced to the centerpoint of the
 aperture ($\bar{R} = \bar{r} - \bar{r}_a$). Note that all angles are input
 in degrees.

FIX -- Logical variable which controls whether or not the
 effects of the cavity walls upon the aperture dipole
 moments are included (See [1], p. 54). If FIX = (.T.),
 such effects are included.

(a)

(b)

DELFIX -- Distance from aperture at which sums are computed
in order to interpolate the deleted Green's functions
(See [1], p. 68)

CHAPTER 3

OUTPUT

File OUTPUT

The program automatically will create the print file OUTPUT. During normal execution, the input information of the previous chapter will be printed, as well as the aperture polarizabilities α_e , $\alpha_{m_{11}}$ and $\alpha_{m_{22}}$ (see [1], p. 17-19). The solution for the wire current and the total aperture fields (E_{T_n} , H_{T_1} , H_{T_2}) are given. For comparison, the exterior short circuit fields (E_n^{sc-} , H_1^{sc-} , H_2^{sc-}) are also given (see [1], pp. 20-26).

In addition, several messages of an informative or warning nature may be printed during execution. These messages which can be divided into three basic categories, are described below:

Informative messages --

1. NOTE--W(I) INTERPOLATED THRU I = n

W(I) is an array containing $P(\alpha)$ for $\alpha = (I-1)\Delta$ (see [1], p. 63). For small α , $P(\alpha)$ is interpolated as discussed on p.65 of [1]. This message indicates that this approximation has been made for the first n values of $P(\alpha)$. To reduce n, increase the size of the input parameter MAX.

Non-Fatal Errors --

1. WARNING -- DIMENSION SIZE EXCEEDED -- name1 TRUNCATED TO n. TO FIX, INCREASE SIZE OF name2 ARRAY(S).

This message indicates that the arrays used for temporary storage in BADSUM, GM1, GM2 and GM3 are not large enough to sum the series to the maximum number of terms specified. The particular input parameter (MAX or MAXX, specified by name1) is truncated and execution is continued. Note that this truncation could subsequently cause either fatal error 5 or 6 listed below. To rectify this problem, increase the size of the array(s) specified by name2, such that $MS1 > \max(MAX, MAXX)$ and $MS2 > \max(c_1 MAX, c_2 MAXX)$ where $c_1 = B/A$ and $c_2 = \max(A, B, C)/\min(A, B, C)$.

Fatal Errors --

1. WARNING--MATRIX SIZE EXCEEDS STORAGE ALLOCATION

The input parameter N is too large. Decrease N and/or increase MS such that $MS \geq N + 3$.

2. WARNING--REORIENT CAVITY SUCH THAT A.LE.B

A must be less than or equal to B. Redefine coordinate system such that this is true.

3. WARNING--ERROR IN WIRE END POINTS

Note that $ZL < ZU$ must be true

4. WARNING--ALL OR PART OF THE WIRE IS OUTSIDE THE CAVITY, OR UN-ATTACHED WIRE HAS END POINT ON CAVITY WALL

Check to see that the input parameters do not violate any of the above conditions.

5. NOT ENOUGH POINTS FOR INTERPOLATION

Interpolation of $P(\alpha)$ requires its numerical evaluation at at least two points. This is not possible with the present input value of MAX. To correct this problem, increase MAX.

6. WARNING--GMI SUM NOT CONVERGED \underline{c} \underline{l}

The value of MAXX is not sufficient to obtain the specified convergence (CS,LS) in GM1, GM2, or GM3. Note that \underline{c} is the convergence ratio at the last term and \underline{l} is the number of consecutive times, if any, the specified convergence ratio CS has been met. To rectify this problem, increase MAXX and/or reduce the severity of the convergence specified by CS and LS.

7. WARNING--SUM 3 NOT CONVERGED \underline{c} \underline{l}

The value of NSM is not sufficient to obtain the specified convergence (CS,LS) in S3. Note that \underline{c} and \underline{l} are defined as in 6 above. To rectify, increase NSM and/or reduce the severity of the convergence specified by CS and LS.

8. WARNING--CAVITY DIMENSION TOO SMALL FOR DPLFIX

This error is caused by insufficient room inside the cavity to perform the interpolation necessary for the evaluation of the deleted Green's functions in SUBROUTINE DPLFIX. To correct, either decrease the size of DELFIX or let FIX = (.F.).

File PUNCH

The program will in certain situations create the punch file PUNCH. This file contains the information from the file INPUT, as

well as the solution for the wire current and the fields ($E_{T_n}, H_{T_1}, H_{T_2}$). The file is formatted according to the PUNCH statements found at the end of PROGRAM START. The PUNCH file will be created only if execution has not been abnormally halted and if sense switch 1 is "on". This can be accomplished on CDC machines with the SCOPE control card ONSW(1).

CHAPTER 4

DESCRIPTION OF PROGRAM AND SUBPROGRAMS

The programs and subprograms listed in this chapter are those used in the code described in this document. Uniformly throughout the following description, it is to be understood that variables (X, Y, Z) represent \bar{r} or (x,y,z) and that (XP,YP,ZP) represent \bar{r}' or (x',y',z'). Similarly, other program variables (denoted in capital letters) obviously represent physical variables of the problem (for example, A, B and C represent the cavity dimensions a, b, and c). Only when such a connection is not obvious will it be explicitly* noted. A complete program listing is given in the appendix.

PROGRAM START

This program's role is primarily that of input/output operations. In addition, it also provides for the checking of consistency among the various input parameters. Finally, it directs program execution by calling the basic matrix filling and inverting subprograms. It is important to note that if the size of the arrays in blank COMMON are changed, the appropriate values of MS, MS1, and MS2 should be changed accordingly to insure proper error checking. Sufficient dimension size can be obtained by adhering to the algorithms listed in chapter 3 under non-fatal error 1 and fatal error 1.

SUBROUTINE FILL

This subroutine fills the matrix \bar{Q}^a (see [1], p.52,63) for the case of an unattached wire. The necessary values of $P(\beta)$ are provided by a call to SUBROUTINE GETUM.

SUBROUTINES FILL1 and FILL2

These subroutines fill the matrix \bar{Q}^a for the cases of the wire attached to the cavity walls at one or both ends respectively. They incorporate the necessary modifications to account for non-zero half-pulse and the half-testing functions which are needed at the attached ends of the wire (see [1], p.50). As in SUBROUTINE FILL, the necessary values of $P(\beta)$ ([1], p.63) are provided by calling SUBROUTINE GETUM.

SUBROUTINE GETUM

This subroutine fills the array $W(I)$ with the necessary values of $P(\beta)$ to fill the matrix. It will automatically interpolate $P(\beta)$ for sufficiently small β (see [1], p.65) using a three-point fit to a second order polynominal in β .

SUBROUTINE MORFIL

This subroutine fills the matrices \bar{Q}^b and \bar{Q}^c according to (4.7) and (4.8) in [1]. In addition it also initializes \bar{Q}^d to \bar{I} , the identity dyad. The necessary components of the dyads have been calculated in SUBROUTINE EAP (through calls to SUBROUTINES EDIPL and MDIPL) and are contained in the arrays FP, G1 and G2. Note that advantage is taken of the fact that $\bar{G}_e(\bar{r}, \bar{r}') = \bar{\tilde{G}}_e(\bar{r}', \bar{r})$ and $\bar{g}_e(\bar{r}, \bar{r}') = -\bar{\tilde{G}}_H(\bar{r}', \bar{r})$ {see [1], Table 2 and (2.7)}.

SUBROUTINE INVERS

This subroutine numerically solves the resulting matrix equation (4.5) in [1] using partial-pivoting Gauss Elimination.

SUBROUTINE FIXUP

This subroutine fills the matrix \bar{Q}^d according to (4.9) in [1]. This routine is called only if the input parameter FIX = (.T.). The values of the deleted Green's functions, which are calculated by SUBROUTINE DPLFIX, are supplied to this subprogram through the common block/WHYNOT/.

SUBROUTINE DPLFIX

This subroutine calculates the deleted Green's functions as outlined on pp. 67-70 of [1]. It is called by START only if FIX = (.T.). Figures 2 (a and b) show arrangement of points at which the components of \bar{G}_A and \bar{g}_F are calculated, respectively. Note that Δ in Figure 2 represents the input parameter DELFIX. These computations are somewhat complicated by the fact that if the aperture is sufficiently close to one or more of the side walls of the cavity the choice of points in Figure 2 must be modified such that all points remain on the cavity interior surface. In addition, when the aperture is close to a side wall, it is necessary to remove the image source in that wall before interpolation, and then to subsequently add it to the interpolated result. Because of these two complications, extensive logic is necessary in DPLFIX to adequately handle them.

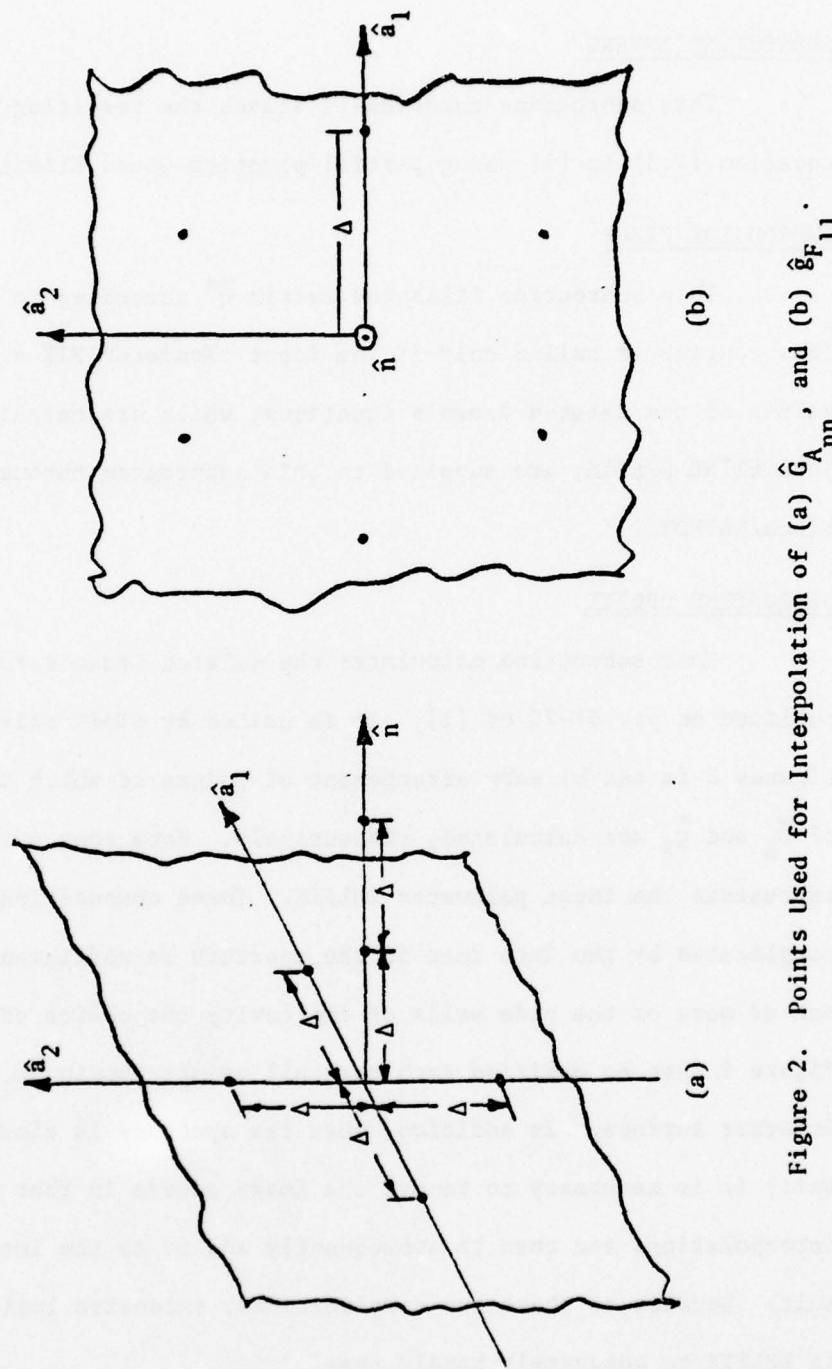

Figure 2. Points Used for Interpolation of (a) $\hat{G}_{A_{nn}}$, and (b) $\hat{g}_{F_{11}}$.

SUBROUTINE EAP

This subroutine calculates several quantities relating to the aperture. It calls subroutines to compute the aperture polarizabilities, and the components of \bar{G}_h and \bar{g}_e necessary to fill \bar{Q}^b and \bar{Q}^c . In addition it calls routines which convert the exterior incident field from the input parameters (shown in Figure 1) to the x,y,z components of E and H. These values are then used to fill the excitation vector in (4.5) of [1] into the array E(I).

SUBROUTINE INC

This subroutine converts the input specifications for the incident field (EMAG,ANG,THE,PHI) to the corresponding components of E and H in the spherical polar coordinate system.

SUBROUTINE CONV

This subroutine converts a vector from its polar components to its cartesian components. It is assumed that the vector is perpendicular to the polar unit vector \hat{f} .

SUBROUTINE ALPHA

This subroutine computes the aperture polarizabilities for the elliptic aperture using (2.15) of [1]. It calls SUBROUTINE ELLIPTIC to provide the necessary values of the elliptic integrals.

SUBROUTINE ELLIPTIC

This subroutine computes the complete elliptic integrals of the first and second kinds of argument X which are denoted EK and E, respectively. They are computed using the polynominal approximations of [2], pp. 591-592.

SUBROUTINE MDIPL

This subroutine calculates $G_{h_{Jz}}(\bar{r}_a, \bar{r}_p)$ for use in the matrix \bar{Q}^c . It fills the array E with these values for $p = 1, N$.

SUBROUTINE EDIPL

This subroutine calculates $G_{e_{Jz}}(\bar{r}_a, \bar{r}_p)$ for use in matrix \bar{Q}^c . It fills the array E with these values for $p = 1, N$. Note that if $ADYAD = (.T.)$, these values are computed indirectly by first computing appropriate values of $G_{A_{zz}}$ and using first-order finite difference techniques.

FUNCTION S3

This function numerically computes the function S_3 , defined by (3.2c) in [1], using (3.16) in [1].

SUBROUTINES GA, GF, GM and GE

These subroutines compute the various components of the dyadic Green's functions needed in the matrices \bar{Q}^b , \bar{Q}^c and \bar{Q}^d (see [1], pp.52-54). Note that these subroutines automatically analytically reduce the sum that will result in the most rapidly converging remaining double sum (see [1], p. 55). Note that IN, SX and SY are dummy arrays and the answer is returned as SD. Table 1 shows the way to call these subroutines to compute any desired dyad component.

SUBROUTINE BADSUM

This subroutine computes the indefinite integral of the reduced kernel $P(\beta)$ defined by (4.22) in [1]. The m-n plane is subdivided into

Table 1. Appropriate subroutine call and value of GEZ to compute the various dyad components.

elliptical bands as discussed on pp. 55-59 of [1] and the double sum is evaluated using the convergence criteria discussed on those pages. If the sum does not converge in the allotted number of terms, the logical variable CIND is set to (.T.) and control is returned to the calling subprogram. SX and SY are input arrays defined as

$$SX(I) = \sin_{k_x} x \sin_{k_x} x' , \quad k_x = \frac{\pi}{a} I$$

and

$$SY(I) = \sin_{k_y} y \sin_{k_y} y' , \quad k_y = \frac{\pi}{b} I$$

The input X represents β and $P(\beta)$ is returned as SD.

SUBROUTINES GMI, GM2 and GM3

These subroutines numerically sum two dimensional series of the following form:

$$GMI = \frac{1}{ab} \sum_{\substack{m=m_0 \\ n=n_0}}^{\infty} \frac{\epsilon_m \epsilon_n u_m v_n w_{mn}}{\gamma_c \sinh \gamma_c}$$

where

$$w_{mn} = \begin{cases} \sinh \gamma_c z < \sinh \gamma_c (c-z) , & I=1 \\ \gamma_c \sinh \gamma_c z \cosh \gamma_c z' , & I=2 \\ \Gamma_1 \cosh \gamma_c z < \cosh \gamma_c (c-z) , & I=3 \end{cases}$$

and

$$\Gamma_1 = \begin{cases} 1 , & GEZ = (.F.) \\ k_c^2 , & GEZ = (.T.) \end{cases}$$

for $k_x = \frac{m\pi}{a}$, $k_y = \frac{n\pi}{b}$, $k_c^2 = k_x^2 + k_y^2$ and $\gamma_c^2 = k_c^2 - k^2$. Note that the input arrays SX and SY are defined as

$$SX(I) = u_{(I-1+m_o)} \text{ and } SY(I) = v_{(I-1+n_o)}$$

and m_o and n_o can each be either 0 or 1. This sum is performed in the same fashion as SUBROUTINE BADSUM and the same convergence criteria is used. Note that if convergence is not achieved, execution is halted and a warning message is printed.

SUBROUTINES NSS, NCC and NSC

These subroutines fill the array D in the following ways:

$$D(I) = \begin{cases} \sin k_x \sin k_x', & (\text{NSS}) \\ \Gamma_2 \cos k_y \cos k_y', & (\text{NCC}) \\ k_z \sin k_z \cos k_z', & (\text{NSC}) \end{cases}$$

where

$$\Gamma_2 = \begin{cases} 1, & \text{GEZ = (.F.)} \\ k_y^2 - k_z^2, & \text{GEZ = (.T.)} \end{cases}$$

$k_x = \frac{\pi}{a} I$, $k_y = \frac{\pi}{b} (I-1)$ and $k_z = \frac{\pi}{c} I$. This subroutine is used to appropriately fill the SX and SY arrays for use in BADSUM, GM1, GM2 or GM3.

SUBROUTINE NDE

This subroutine is a dummy routine to call either NSS, NCC or NSC, depending upon the value of the integer L.

FUNCTIONS COSH and SINH

These functions compute the hyperbolic cosine and sine, respectively, of argument X.

FUNCTIONS RSS, RCC, RCS and RSINH

These functions compute the ratios of various combinations of hyperbolic functions. They are defined by

$$RSS(X, Y, Z) = \frac{\sinh X \sinh Y}{\sinh Z}$$

$$RCC(X, Y, Z) = \frac{\cosh X \cosh Y}{\sinh Z}$$

$$RCS(X, Y, Z) = \frac{\cosh X \sinh Y}{\sinh Z}$$

and

$$RSINH(X, Y) = \frac{\sinh X}{\sinh Y}.$$
